## 1. Introduction

ILI9341 is a 262,144-color single-chip SOC driver for a-TFT liquid crystal display with resolution of 240RGBx320 dots, comprising a 720-channel source driver, a 320-channel gate driver, 172,800 bytes GRAM for graphic display data of 240RGBx320 dots, and power supply circuit.

ILI9341 supports parallel 8-/9-/16-/18-bit data bus MCU interface, 6-/16-/18-bit data bus RGB interface and 3-/4-line serial peripheral interface (SPI). The moving picture area can be specified in internal GRAM by window address function. The specified window area can be updated selectively, so that moving picture can be displayed simultaneously independent of still picture area.

ILI9341 can operate with 1.65V ~ 3.3V I/O interface voltage and an incorporated voltage follower circuit to generate voltage levels for driving an LCD. ILI9341 supports full color, 8-color display mode and sleep mode for precise power control by software and these features make the ILI9341 an ideal LCD driver for medium or small size portable products such as digital cellular phones, smart phone, MP3 and PMP where long battery life is a major concern.

**Note.**

1. If CSX is connected to VSS in Parallel interface mode, there will be no abnormal visible effect to the display module. Also there will be no restriction on using the Parallel Read/Write protocols, Power On/Off Sequences or other functions. Furthermore there will be no influence to the Power Consumption of the display module.
2. When CSX='1', there is no influence to the parallel and serial interface.

**7.1.2. 8080- I Series Parallel Interface**

ILI9341 can be accessed via 8-/9-/16-/18-bit MCU 8080- I series parallel interface. The chip-select CSX (active low) is used to enable or disable ILI9341 chip. The RESX (active low) is an external reset signal. WRX is the parallel data write strobe, RDX is the parallel data read strobe and D[17:0] is parallel data bus.

ILI9341 latches the input data at the rising edge of WRX signal. The D/CX is the signal of data/command selection. When D/CX='1', D [17:0] bits are display RAM data or command's parameters. When D/CX='0', D [17:0] bits are commands.

The 8080- I series bi-directional interface can be used for communication between the MCU controller and LCD driver chip. The 8080- I Interface selection is done when IM3 pin is low state (VSS level). Interface bus width can be selected by IM [2:0] bits.

The selection of 8080- I series parallel interface is shown as the table in the following.

| IM3 | IM2 | IM1 | IM0 | MCU-Interface Mode              | CSX | WRX | RDX | D/CX | Function                         |

### 7.1.3. Write Cycle Sequence

The WRX signal is driven from high to low and then be pulled back to high during the write cycle. The host processor provides information during the write cycle when the display module captures the information from host processor on the rising edge of WRX. When the D/CX signal is driven to low level, then input data on the interface is interpreted as command information. The D/CX signal also can be pulled high level when the data on the interface is RAM data or command's parameter.

The following figure shows a write cycle for the 8080- I MCU interface.

Note: WRX is an unsynchronized signal (It can be stopped)

### 7.1.4. Read Cycle Sequence

The RDX signal is driven from high to low and then allowed to be pulled back to high during the read cycle. The display module provides information to the host processor during the read cycle while the host processor reads the display module information on the rising edge of RDX signal. When the D/CX signal is driven to low level, then input data on the interface is interpreted as command. The D/CX signal also can be pulled high level when the data on the interface is RAM data or command parameter.

The following figure shows the read cycle for the 8080- I MCU interface.

Note: RDX is an unsynchronized signal (It can be stopped).

Note: Read data is only valid when the D/CX input is pulled high. If D/CX is driven low during read then the display information outputs will be High-Z.

### 7.1.5. 8080- II Series Parallel Interface

ILI9341 can be accessed via 8-/9-/16-/18-bit MCU 8080- II series parallel interface. The chip-select CSX (active low) is used to enable or disable ILI9341 chip. The RESX (active low) is an external reset signal. WRX is the parallel data write strobe, RDX is the parallel data read strobe and D[17:0] is parallel data bus.

ILI9341 latches the input data at the rising edge of WRX signal. The D/CX is the signal of data/command selection. When D/CX='1', D [17:0] bits are display RAM data or command's parameters. When D/CX='0', D [17:0] bits are commands.

The 8080- II series bi-directional interface can be used for communication between the MCU controller and LCD driver chip. The 8080- II Interface selection is done when IM3 pin is high state (VDDI level). Interface bus width can be selected by IM [2:0] bits.

The selection of 8080- II series parallel interface is shown as the table in the following.

| IM3 | IM2 | IM1 | IM0 | MCU-Interface Mode               | CSX | WRX   | RDX   | D/CX | Function                         |

### 7.1.6. Write Cycle Sequence

The WRX signal is driven from high to low and then be pulled back to high during the write cycle. The host processor provides information during the write cycle when the display module captures the information from host processor on the rising edge of WRX. When the D/CX signal is driven to low level, then input data on the interface is interpreted as command information. The D/CX signal also can be pulled high level when the data on the interface is RAM data or command's parameter.

The following figure shows a write cycle for the 8080- II MCU interface.

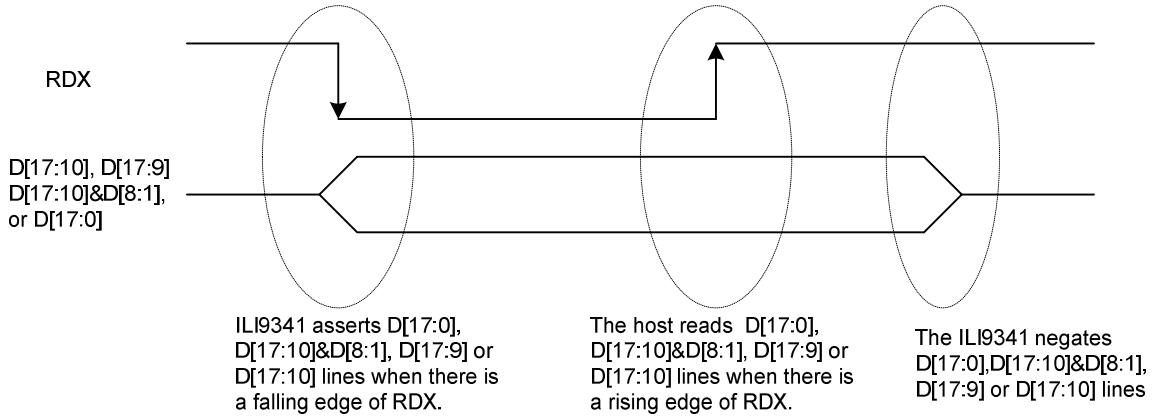

Note: WRX is an unsynchronized signal (It can be stopped)

### 7.1.7. Read Cycle Sequence

The RDX signal is driven from high to low and then allowed to be pulled back to high during the read cycle. The display module provides information to the host processor during the read cycle while the host processor reads the display module information on the rising edge of RDX signal. When the D/CX signal is driven to low level, then input data on the interface is interpreted as command. The D/CX signal also can be pulled high level when the data on the interface is RAM data or command parameter.

The following figure shows the read cycle for the 8080- II MCU interface.

Note: RDX is an unsynchronized signal (It can be stopped).

Note: Read data is only valid when the D/CX input is pulled high. If D/CX is driven low during read then the display information outputs will be High-Z.

### 7.1.8. Serial Interface

The selection of interface is done by IM [3:0] bits. Please refer to the Table in the following.

| IM3 | IM2 | IM1 | IM0 | MCU-Interface Mode      | CSX | D/CX  | SCL | Function                                       |
|-----|-----|-----|-----|-------------------------|-----|-------|-----|--|
| 0   | 1   | 0   | 1   | 3-line serial interface | "L" | -     | ┐   | Read/Write command, parameter or display data. |
| 0   | 1   | 1   | 0   | 4-line serial interface | "L" | 'H/L' | ┐   | Read/Write command, parameter or display data. |
| 1   | 1   | 0   | 1   | 3-line serial interface | "L" | -     | ┐   | Read/Write command, parameter or display data. |
| 1   | 1   | 1   | 0   | 4-line serial interface | "L" | 'H/L' | ┐   | Read/Write command, parameter or display data. |

ILI9341 supplies 3-lines/ 9-bit and 4-line/8-bit bi-directional serial interfaces for communication between host and ILI9341. The 3-line serial mode consists of the chip enable input (CSX), the serial clock input (SCL) and serial data Input/Output (SDA or SDI/SDO). The 4-line serial mode consists of the Data/Command selection input (D/CX), chip enable input (CSX), the serial clock input (SCL) and serial data Input/Output (SDA or SDI/SDO) for data transmission. The data bus (D [17:0]), which are not used, must be connected to GND. Serial clock (SCL) is used for interface with MCU only, so it can be stopped when no communication is necessary.

### 7.1.9. Write Cycle Sequence

The write mode of the interface means that host writes commands or data to ILI9341. The 3-lines serial data packet contains a data/command select bit (D/CX) and a transmission byte. If the D/CX bit is "low", the transmission byte is interpreted as a command byte. If the D/CX bit is "high", the transmission byte is stored as the display data RAM (Memory write command), or command register as parameter.

Any instruction can be sent in any order to ILI9341 and the MSB is transmitted first. The serial interface is initialized when CSX is high status. In this state, SCL clock pulse and SDA data are no effect. A falling edge on CSX enables the serial interface and indicates the start of data transmission. See the detailed data format for 3-/4-line serial interface.

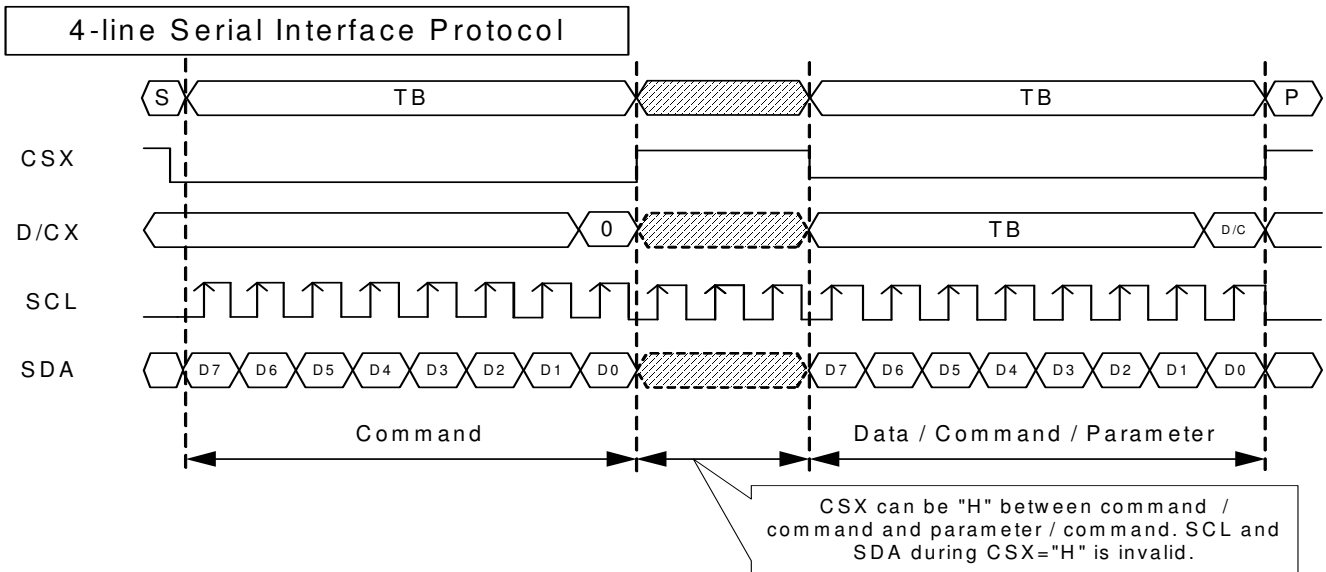

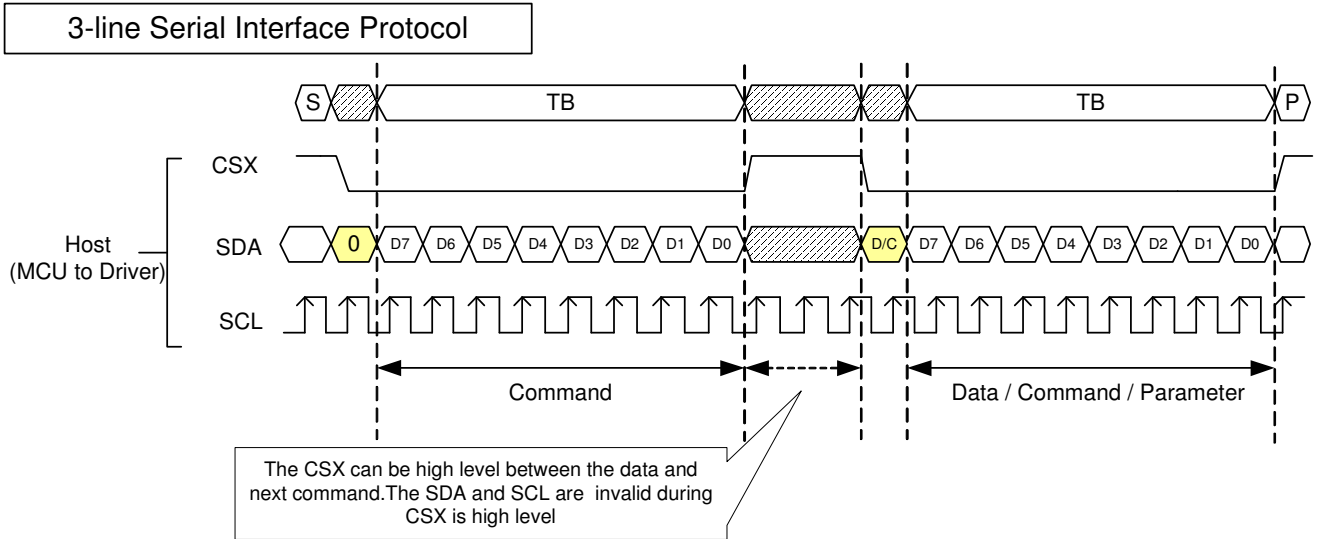

**Data Format for 3-line Serial Interface**

Data Format for 4-line Serial Interface

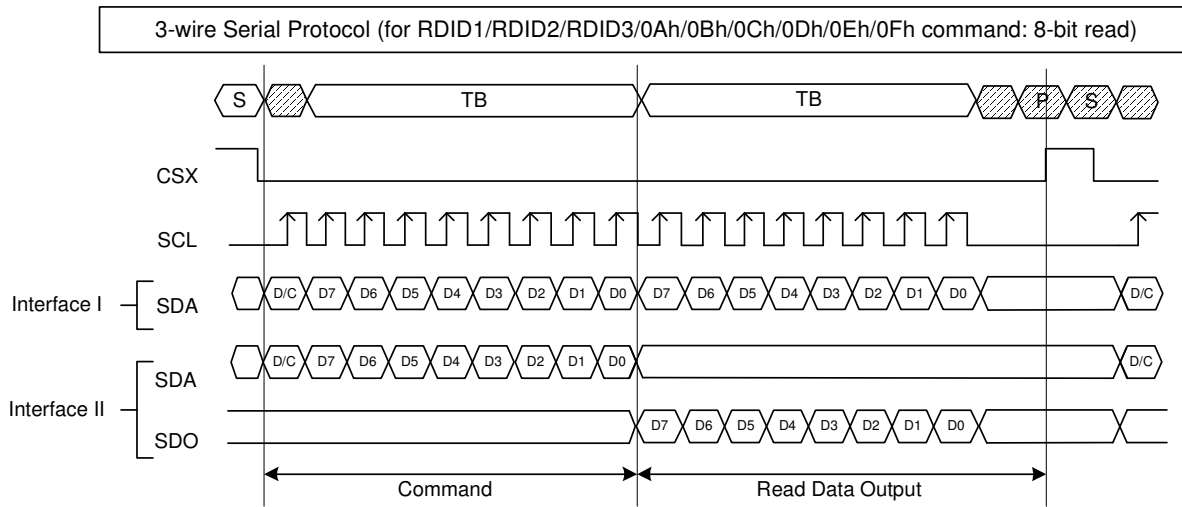

Host processor drives the CSX pin to low and starts by setting the D/CX bit on SDA. The bit is read by ILI93401 on the first rising edge of SCL signal. On the next falling edge of SCL, the MSB data bit (D7) is set on SDA by the host. On the next falling edge of SCL, the next bit (D6) is set on SDA. If the optional D/CX signal is used, a byte is eight read cycle width. The 3/4-line serial interface writes sequence described in the figure as below.

### 7.1.10. Read Cycle Sequence

The read mode of interface means that the host reads register's parameter or display data from ILI9341. The host has to send a command (Read ID or register command) and then the following byte is transmitted in the opposite direction. ILI9341 latches the SDA (input data) at the rising edges of SCL (serial clock), and then shifts SDA (output data) at falling edges of SCL (serial clock). After the read status command has been sent, the SDA line must be set to tri-state and no later than at the falling edge of SCL of the last bit. The read mode has three types of transmitted command data (8-/24-/32-bit) according to command code.

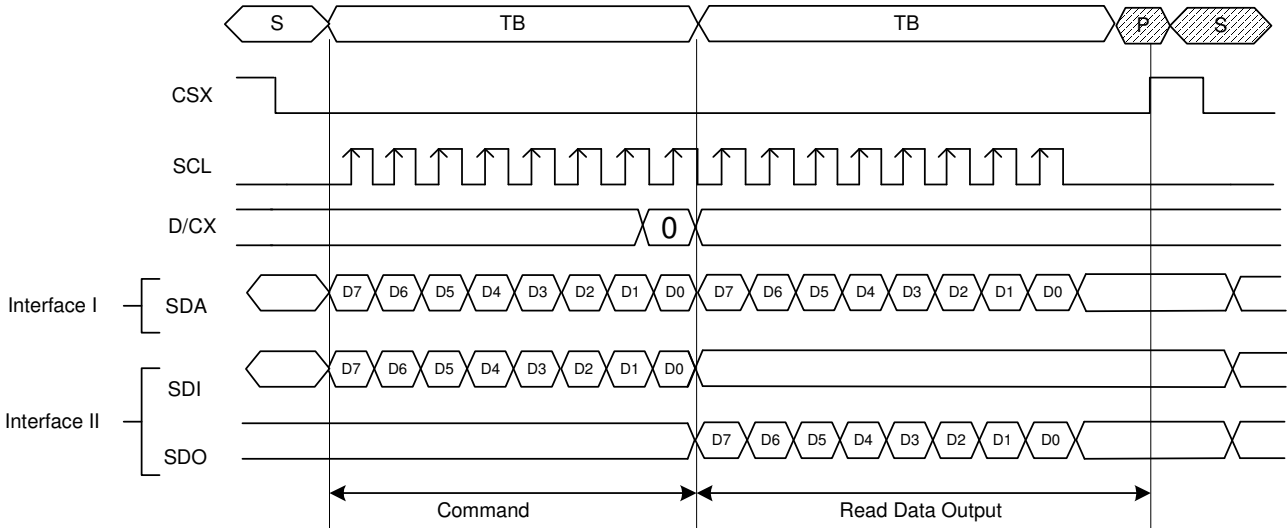

#### 3-wire Serial Interface Protocol

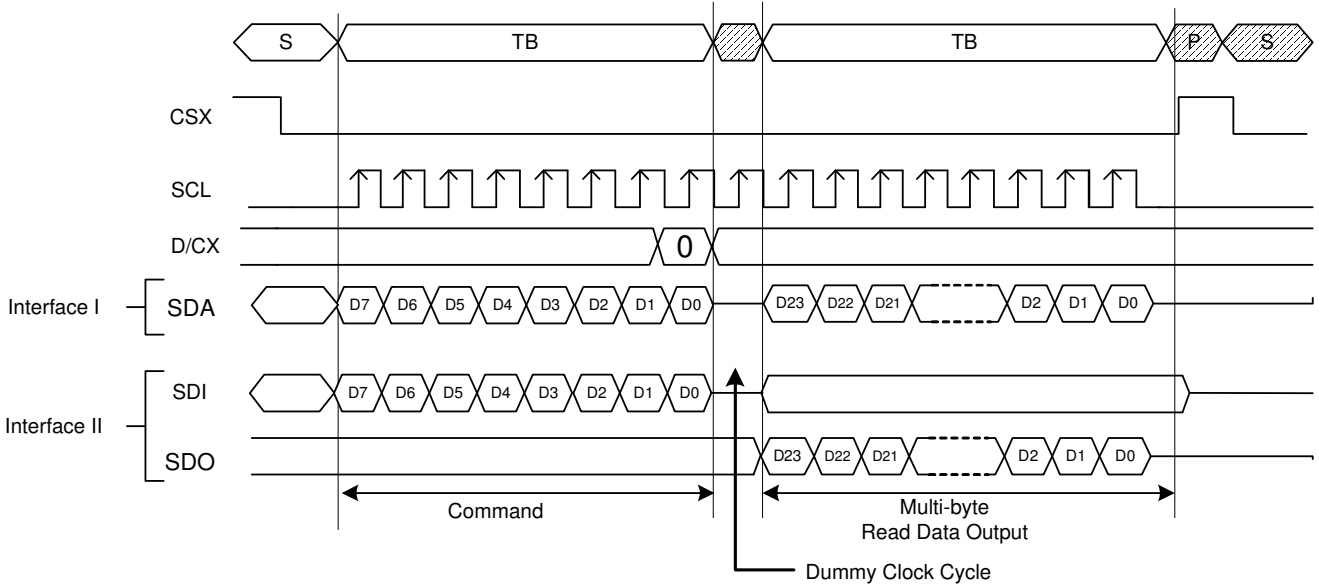

**4-wire Serial Interface Protocol**

4-wire Serial Protocol (for RDID1/RDID2/RDID3/0Ah/0Bh/0Ch/0Dh/0Eh/0Fh command: 8-bit read)

4-wire Serial Protocol (for RDDID command: 24-bit read)

**7.1.11. Data Transfer Break and Recovery**

If there is a break in data transmission by RESX pulse, while transferring a command or frame memory data or multiple parameter command data, before Bit D0 of the byte has been completed, then the driver will reject the previous bits and have reset the interface such that it will be ready to receive command data again when the chip select pin (CSX) is activated after RESX have been high state.

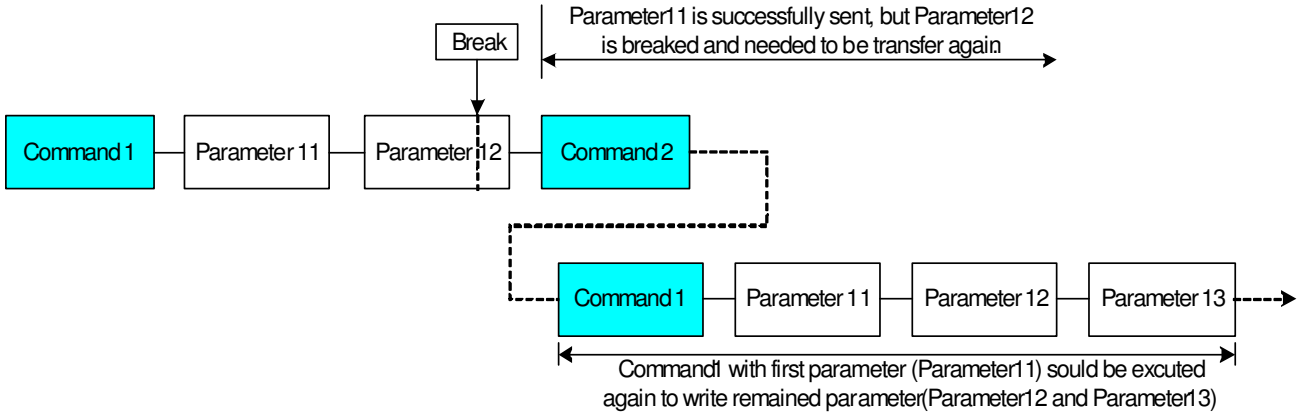

If there is a break in data transmission by CSX pulse, while transferring a command or frame memory data or multiple parameter command data, before Bit D0 of the byte has been completed, then the driver will reject the previous bits and have reset the interface such that it will be ready to receive the same byte re-transmitted when the chip select pin (CSX) is next activated.

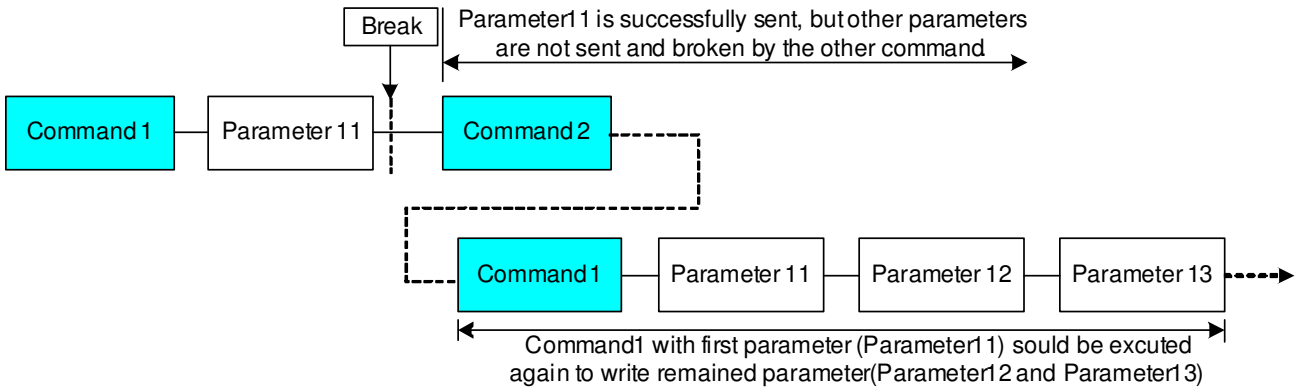

If a two or more parameter command is being sent and a break occurs while sending any parameter before the last one and if the host then sends a new command rather than continue to send the remained parameters that was interrupted, then the parameters which had been successfully sent are stored and the parameter where the break occurred is rejected. The interface is ready to receive next byte as shown below.

If a two or more parameter command is being sent and a break occurs by the other command before the last one is sent, then the parameters which had been successfully sent are stored and the other parameter of that command remains previous value.

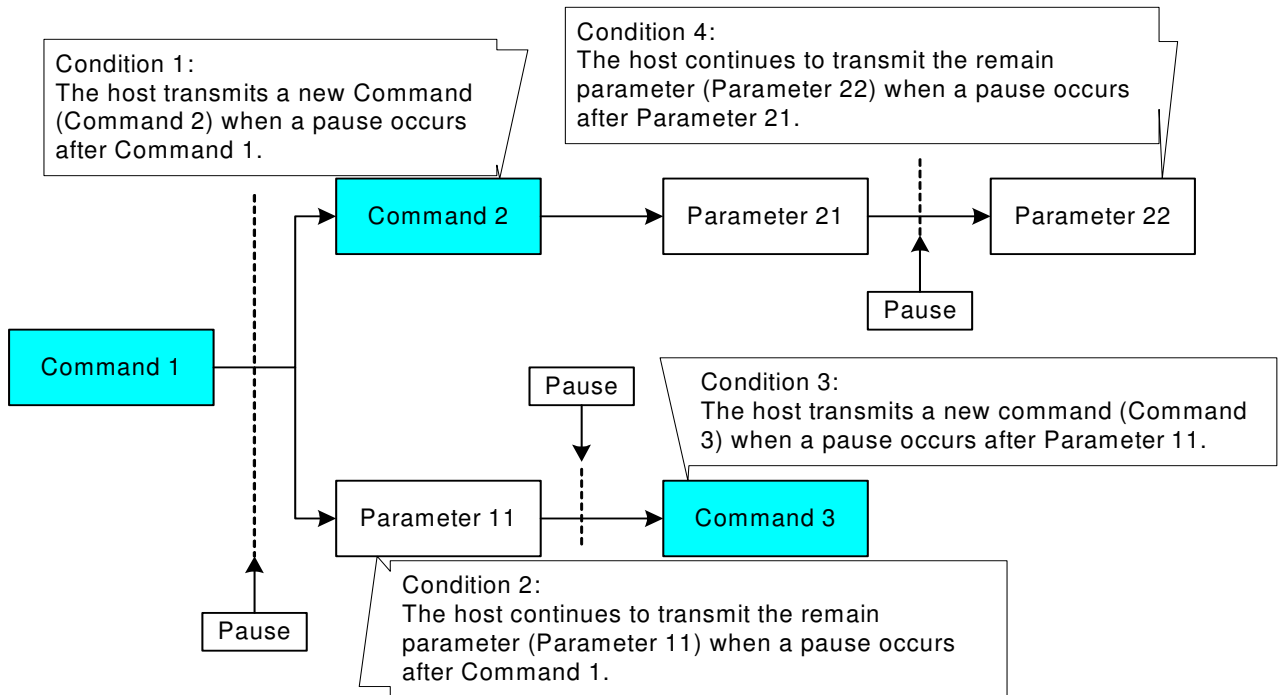

### 7.1.12. Data Transfer Pause

It will be possible when transferring a command, frame memory data or multiple parameter data to invoke a pause in the data transmission. If the chip select pin (CSX) is released to high state after a whole byte of a frame memory data or multiple parameter data has been completed, then ILI9341 will wait and continue the frame memory data or parameter data transmission from the point where it was paused. If the chip select pin is released after a whole byte of a command has been completed, then the display module will receive either the command's parameters (if appropriate) or a new command when the chip select pin is next enabled as shown below.

This applies to the following 4 conditions:

- 1) Command-Pause-Command
- 2) Command-Pause-Parameter
- 3) Parameter-Pause-Command
- 4) Parameter-Pause-Parameter

**7.1.13. Serial Interface Pause (3\_wire)**

**7.1.14. Parallel Interface Pause**

### 7.1.15. Data Transfer Mode

ILI9341 can provide two different kinds of color depth (16-bit/pixel and 18-bit/pixel) display data to the graphic RAM. The data format is described for each interface. Data can be downloaded to the frame memory by 2 methods.

### 7.1.16. Data Transfer Method 1

The image data is sent to the frame memory in the successive frame writing, each time the frame memory is filled by image data, the frame memory pointer is reset to the start point and the next frame is written.

### 7.1.17. Data Transfer Method 2

Image data is sent and at the end of each frame memory download, a command is sent to stop frame memory writing. Then start memory write command is sent, and a new frame is downloaded.

*Note 1: These methods are applied to all data transfer color modes on both serial and parallel interfaces.*

*Note 2: The frame memory can contain both odd and even number of pixels for both methods. Only complete pixel data will be stored in the frame memory.*

## 7.2. RGB Interface

### 7.2.1. RGB Interface Selection

ILI9341 has two kinds of RGB interface and these interfaces can be selected by RCM [1:0] bits. When RCM [1:0] bits are set to “10”, the DE mode is selected which utilizes VSYNC, HSYNC, DOTCLK, DE, D [17:0] pins; when RCM [1:0] bits are set to “11”, the SYNC mode is selected which utilizes which utilizes VSYNC, HSYNC, DOTCLK, D [17:0] pins. Using RGB interface must selection serial interface.

ILI9341 supports several pixel formats that can be selected by DPI [2:0] bits of “Pixel Format Set (3Ah)” and RIM bit of RF6h command. The selection of a given interfaces is done by setting RCM [1:0] and DPI [2:0] as show in the following table.

| RCM[1:0] |   | RIM | DPI[2:0] |   |   | RGB Interface Mode                 | RGB Mode   | Used Pins                                    |

Pixel clock (DOTCLK) is running all the time without stopping and used to enter VSYNC, HSYNC, DE and D [17:0] states when there is a rising edge of the DOTCLK. Vertical synchronization (VSYNC) is used to tell when

*The information contained herein is the exclusive property of ILI Technology Corp. and shall not be distributed, reproduced, or disclosed in whole or in part without prior written permission of ILI Technology Corp.*

there is received a new frame of the display. This is low enable and its state is read to the display module by a rising edge of the DOTCLK signal.

Horizontal synchronization (HSYNC) is used to tell when there is received a new line of the frame. This is low enable and its state is read to the display module by a rising edge of the DOTCLK signal.

In DE mode, Data Enable (DE) is used to tell when there is received RGB information that should be transferred on the display. This is a high enable and its state is read to the display module by a rising edge of the DOTCLK signal. D [17:0] are used to tell what is the information of the image that is transferred on the display (When DE= '0' (low) and there is a rising edge of DOTCLK). D [17:0] can be '0' (low) or '1' (high). These lines are read by a rising edge of the DOTCLK signal. In SYNC mode, the valid display data is inputted in pixel unit via D [17:0] according to HFP/HBP settings of HSYNC signal and VFP/VBP setting of VSYNC. In both RGB interface modes, the input display data is written to GRAM first then outputs corresponding source voltage according the gray data from GRAM.

frequency about 70Hz.

Notes:

1. Vertical period (one frame) shall be equal to the sum of  $V_{sync} + VBP + VAdr + VFP$ .
2. Horizontal period (one line) shall be equal to the sum of  $Hsync + HBP + HAdr + HFP$ .
3. Control signals PCLK and Hsync shall be transmitted as specified at all times while valid pixels are transferred between the host processor and the display module.

Also make sure that

(Number of PCLK per 1 line)  $\geq$  (Number of RTN clock) x Division ratio (DIV) x PCDIV

#### Setting Example for Display Control Clock in RGB Interface Operation

Register Display operation using DPI is in synchronization with internal clock PCLKD which is generated by dividing DOTCLK.

**PCDIV [5:0]:** Number of DOTCLK during internal clock PCLKD's high / low period. In units of 1 clock.

PCDIV specifying DOTCLK's division ratio, are determined so that difference between PCLKD's frequency and internal oscillation clock 615KHz is the smallest. Set PCDIV follow the restriction

(Number of PCLK in 1H)  $\geq$  (Number of RTN clock) x Division ratio (DIV) x PCDIV.

**Setting Example:** To set frame frequency to 70Hz:

#### Internal Clock

Internal Oscillation Clock: 615KHz

DIV[1:0] = 2'b0 (x 1/1)

RTN[4:0] = 5'h1b (27 clocks)

FP = 7'h2 (2 lines), BP = 7'h2 (2 lines), NL = 6'h27 (320 lines)

**Frame Rate  $\rightarrow$  70.30Hz**

#### DOTCLK

HSYNC = 10 CLK

HBP = 20 CLK

HFP=10 CLK

70Hz x (2 + 320 + 2) lines x (10 + 20 + 240 + 10) clocks = 6.35MHz

DOTCLK frequency = 6.35MHz

6.35 MHz / 615KHz = 10.32  $\square$  Set PCDIV so that PCLK is divided by 10.

external fosc = 6.35 MHz / 10 = 635KHz

PCDIV = [ 6.35MHz / 635KHz / 2 ] - 1 = 4

PCDIV[5:0] = 6'h04 (10 DOTCLK)

### 7.2.2. RGB Interface Timing

The timing chart of 18-/16-bit RGB interface mode is shown as below.

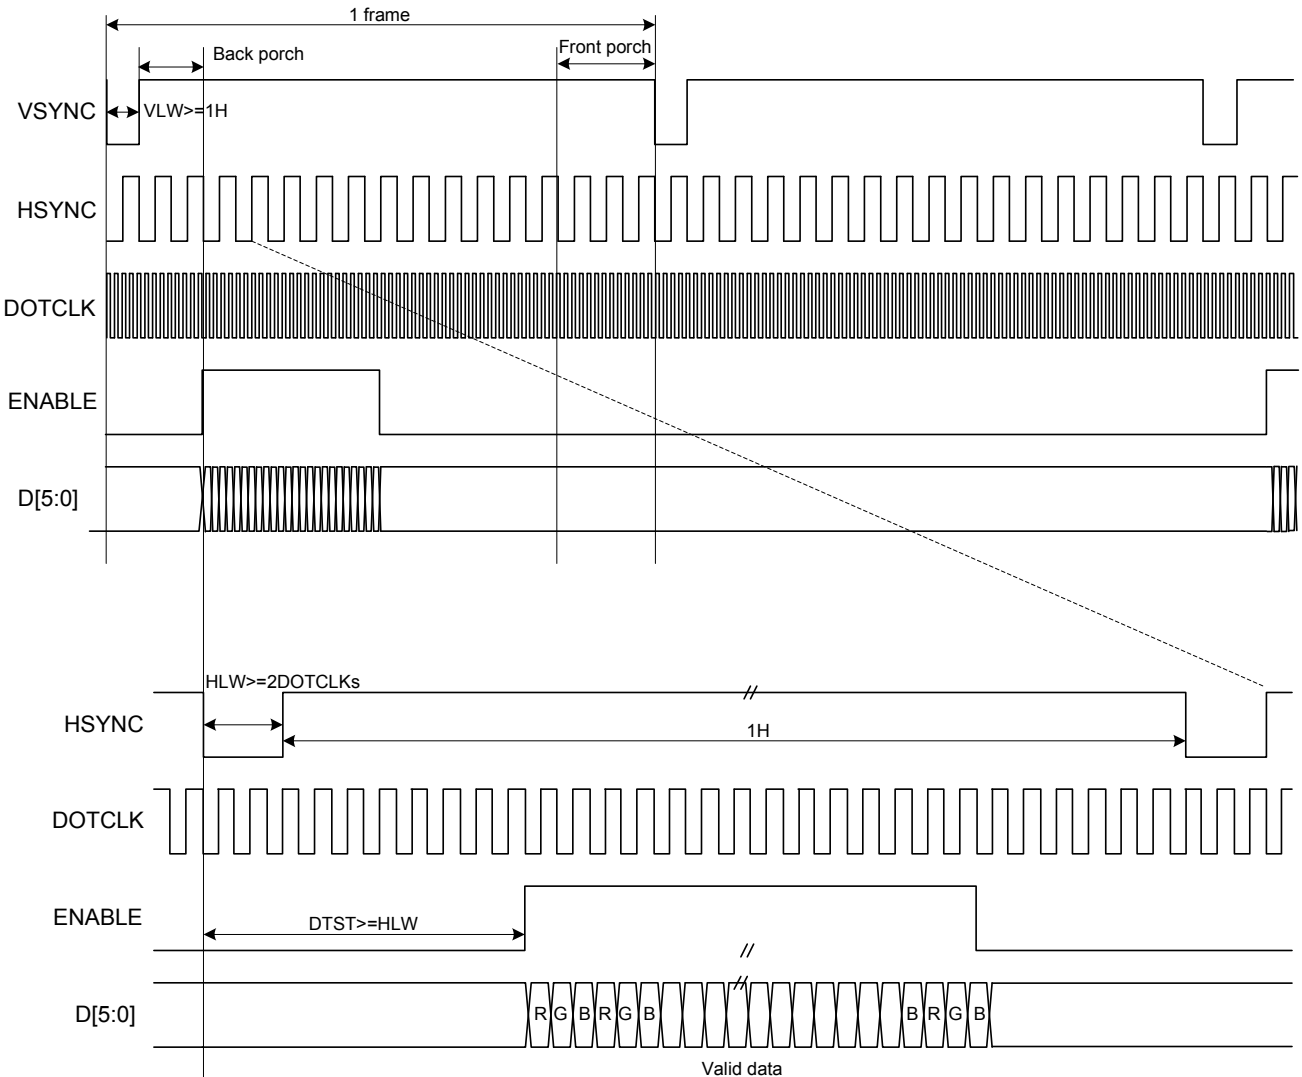

VLW : VSYNC Low Width  
HLW : HSYNC Low Width  
DTST : Data Transfer Startup Time

Note 1: The DE signal is not needed when RGB interface SYNC mode is selected.

Note 2: VSPL='0', HSPL='0', DPL='0' and EPL='0' of "Interface Mode Control (B0h)" command.

The timing chart of 6-bit RGB interface mode is shown as below:

VLW : VSYNC Low Width  
HLW : HSYNC Low Width  
DTST : Data Transfer Startup Time

- Note 1: The DE signal is not needed when RGB interface SYNC mode is selected.
- Note 2: VSPL='0', HSPL='0', DPL='0' and EPL='0' of "Interface Mode Control (B0h)" command.
- Note 3: In 6-bit RGB interface mode, each dot of one pixel (R, G and B) is transferred in synchronization with DOTCLK.

*Note 4: In 6-bit RGB interface mode, set the cycles of VSYNC, HSYNC and DE to 3 multiples of DOTCLK.*

### 7.3. VSYNC Interface

ILI9341 supports the VSYNC interface in synchronization with the frame-synchronizing signal VSYNC to display the moving picture with the 8080- I /8080- II system interface. When the VSYNC interface is selected to display a moving picture, the minimum GRAM update speed is limited and the VSYNC interface is enabled by setting DM[1:0] = "10" and RM = "0".

In the VSYNC mode, the display operation is synchronized with the internal clock and VSYNC input and the frame rate is determined by the pulse rate of VSYNC signal. All display data are stored in GRAM to minimize total data transfer required for moving picture display.

The VSYNC interface has the minimum speed limitation of writing data to the internal GRAM via the system interface, which are calculated from the following formula.

*Internal clock frequency (fosc.) [Hz] = FrameFrequency x (DisplayLine (NL) + FrontPorch (VFP) + BackPorch (VBP)) x ClockCyclePerLines (RTN) x FrequencyFluctuation.*

$$\text{Minimum RAM write speed [Hz]} > \frac{240 \times \text{DisplayLines(NL)}}{[\text{BackPorch(VBP)} + \text{DisplayLines(NL)} - \text{margins}] \times \text{Clocks per line} \times (1/\text{fosc})}$$

*Note: When the RAM write operation does not start from the falling edge of VSYNC, the time from the falling edge of VSYNC until the start of RAM write operation must also be taken into account.*

An example of minimum GRAM writing speed and internal clock frequency in VSYNC interface mode is as below.

**[Example]**

- Display size: 240 RGB x 320 lines
- Lines: 320 lines (NL = 100111)
- Back porch: 2 lines (VBP = 0000010)
- Front porch: 2 lines (VFP = 0000010)
- Frame frequency: 70 Hz
- Frequency fluctuation: 10%

*Internal oscillator clock (fosc.) [Hz] = 70 x [320+ 2 + 2] x 27 clocks x (1.1/0.9) ≐ 748KHz*

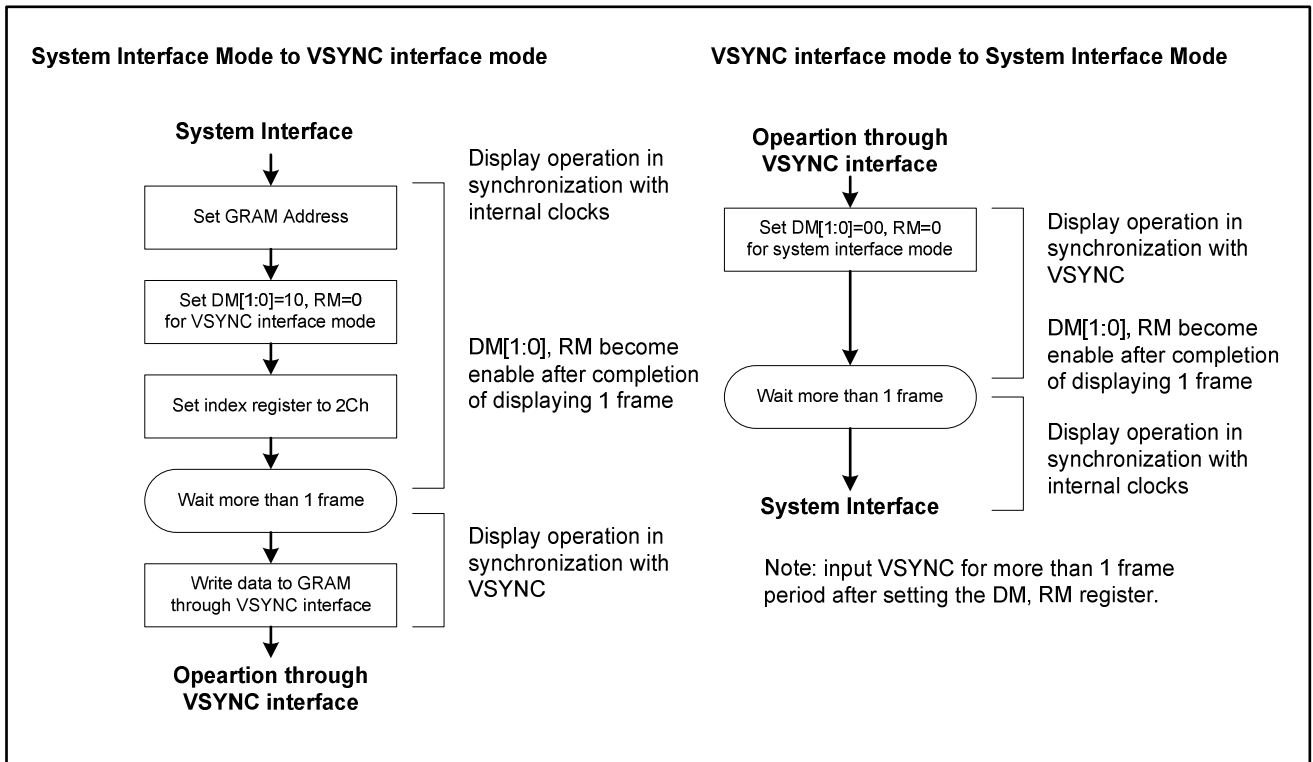

When calculate the internal clock frequency, the oscillator variation is needed to be taken into consideration. In the above example, the calculated internal clock frequency with  $\pm 10\%$  margin variation is considered and ensures to complete the display operation within one VSYNC cycle. The causes of frequency variation come from fabrication process of LSI, room temperature, external resistors and VCI voltage variation.

$$\text{Minimum speed for RAM writing [Hz]} > 240 \times 320 \times 748K / [(2 + 320 - 2)\text{lines} \times 27\text{clocks}] \doteq 6.65 \text{ MHz}$$

The above theoretical value is calculated based on the premise that the ILI9341 starts to write data into the internal GRAM on the falling edge of VSYNC. There must at least be a margin of 2 lines between the physical display line and the GRAM line address where data writing operation is performed. The GRAM write speed of 6.65MHz or more will guarantee the completion of GRAM write operation before the ILI9341 starts to display the GRAM data on the screen and enable to rewrite the entire screen without flicker.

**Notes in using the VSYNC interface**

1. The minimum GRAM write speed must be satisfied and the frequency variation must be taken into consideration.
2. The display frame rate is determined by the VSYNC signal and the period of VSYNC must be longer than the scan period of an entire display.
3. When switching from the internal clock operation mode (DM[1:0] = "00") to the VSYNC interface mode or inversely, the switching starts from the next VSYNC cycle, i.e. after completing the display of the frame.
4. The partial display, vertical scroll, and interlaced scan functions are not available in VSYNC interface mode.

## 7.4. Color Depth Conversion Look Up Table

When ILI9341 operates in parallel 16-bit interface, the color depth conversion is done by look-up table and extend input data format to 18-bit. See the detailed for look-up table of color depth conversion.

## **7.5. Display Data RAM (DDRAM)**

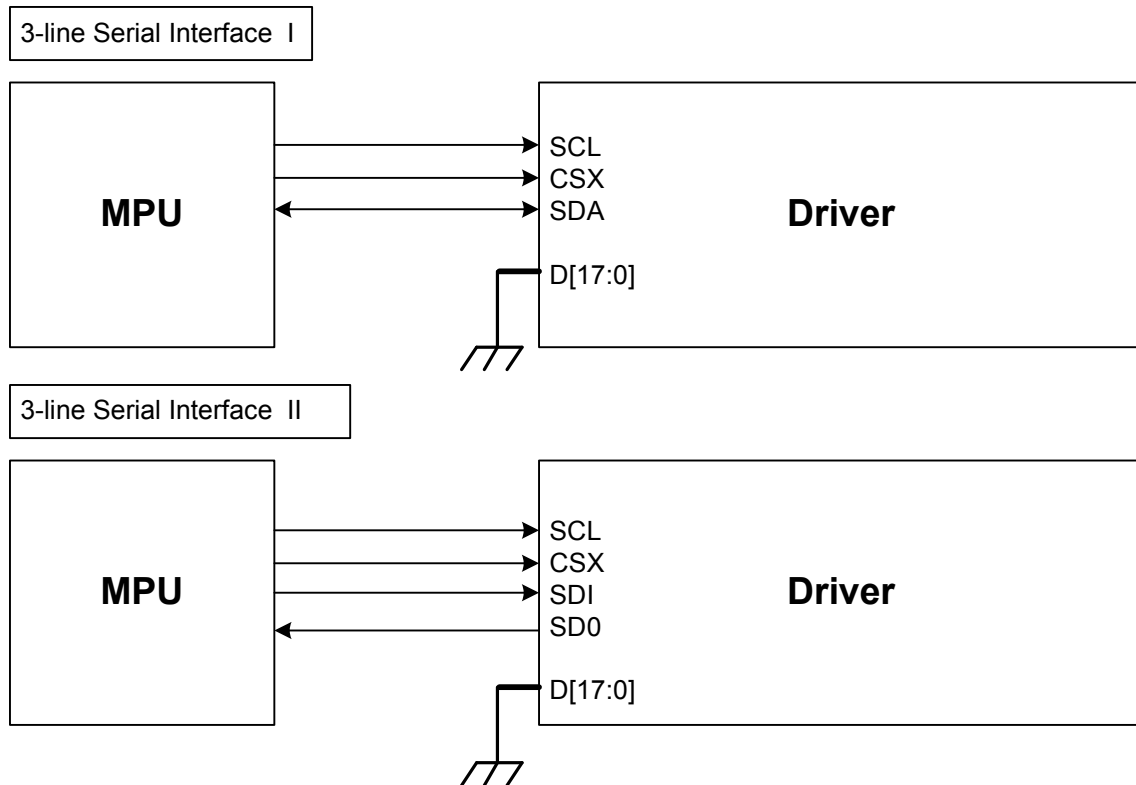

ILI9341 has an integrated 240x320x18-bit graphic type static RAM. This 172,800-byte memory allows storing a 240xRGBx320 image with an 18-bit resolution (262K-color). There is no abnormal visible effect on the display when there are simultaneous panel display read and interface read/write to the same location of the frame memory.

## 7.6. Display Data Format

ILI9341 supplies 18-/16-/9-/8-bit parallel MCU interface with 8080- I /8080- II series, 3-/4-line serial interface and 6-/16-18-bit parallel RGB interface. The parallel MCU interface and serial interface mode can be selected by external pins IM [3:0] and RGB interface mode can be selected by software command parameters RCM[1:0].

### 7.6.1. 3-line Serial Interface

The 3-line/9-bit serial bus interface of ILI9341 can be used by setting external pin as IM [3:0] to “0101” for serial interface I or IM [3:0] to “1101” for serial interface II. The shown figure is the example of 3-line SPI interface.

In 3-line serial interface, different display data format is available for two color depths supported by the LCM listed below.

- 65k colors, RGB 5, 6, 5 -bits input
- 262k colors, RGB 6, 6, 6 -bits input.

**16 bit/pixel color order (R:5-bit, G:6-bit, B:5-bit), 65,536 colors**

Note 1: The pixel data with 16-bit color depth information.

Note 2: The most significant bits are: Rx4, Gx5 and Bx4.

Note 3: The least significant bits are: Rx0, Gx0 and Bx0.

### 7.6.7. 6-bit Parallel RGB Interface

The 6-bit RGB interface is selected by setting the DPI [2:0] bit to “110”. When RCM [1:0] are set to “10” and DE mode is selected, the display operation is synchronized with VSYNC, HSYNC and DOTCLK signals. The display data are transferred to the internal GRAM in synchronization with the display operation via 6-bit RGB data bus (D [5:0]) according to the data enable signal (DE) when RCM [1:0] are set to “10”. The RGB interface SYNC mode is selected by setting the RCM [1:0] to “11”, the valid display data is inputted in pixel unit via D [5:0] according to the VFP/VBP and HFP/HBP settings. Unused pins must be connected to GND to ensure normally operation. Registers can be set by the SPI system interface.

#### 65K color: 16-bit/pixel (RGB 5-6-5 bits input)

#### 262K color: 18-bit/pixel (RGB 6-6-6 bits input)

ILI9341 has data transfer counters to count the first, second, third data transfer in 6-bit RGB interface mode. The transfer counter is always reset to the state of first data transfer on the falling edge of VSYNC. If a mismatch arises in the number of each data transfer, the counter is reset to the state of first data transfer at the start of the frame (i.e. on the falling edge of VSYNC) to restart data transfer in the correct order from the next frame. This function is expedient for moving picture display, which requires consecutive data transfer in light of minimizing effects from failed data transfer and enabling the system to return to a normal state.

Note that internal display operation is performed in units of pixels (RGB: taking 3 inputs of DOTCLK). Accordingly, the number of DOTCLK inputs in one frame period must be a multiple of 3 to complete data transfer correctly. Otherwise it will affect the display of that frame as well as the next frame.

**DE Mode, RCM[1:0]="10"**

### 7.6.8. 16-bit Parallel RGB Interface

The 16-bit RGB interface is selected by setting the DPI [2:0] bits to “101”. When RCM [1:0] are set to “10” and DE mode is selected, the display operation is synchronized with VSYNC, HSYNC and DOTCLK signals. The display data is transferred to the internal GRAM in synchronization with the display operation via 16-bit RGB data bus (D [17:13] & D [11:1]) according to the data enable signal (DE). The RGB interface SYNC mode is selected by setting the RCM [1:0] to “11”, the valid display data is inputted in pixel unit via D [17:13] and D [11:1] according to the VFP/VBP and HFP/HBP settings. The unused D12 and D0 pins must be connected to GND for ensure normally operation. Registers can be set by the SPI system interface.

### 7.6.9. 18-bit Parallel RGB Interface

The 18-bit RGB interface is selected by setting the DPI [2:0] bits to “110”. When RCM [1:0] are set to “10” and DE mode is selected, the display operation is synchronized with VSYNC, HSYNC and DOTCLK signals. The display data are transferred to the internal GRAM in synchronization with the display operation via 18-bit RGB data bus (D [17:0]) according to the data enable signal (DE) when RCM [1:0] are set to “10”. The RGB interface SYNC mode is selected by setting the RCM [1:0] to “11”, the valid display data is inputted in pixel unit via D [17:0] according to the VFP/VBP and HFP/HBP settings. Registers can be set by the SPI system interface.

A dashed line separates the Host (top) from the Driver (bottom). A trapezoidal shape labeled 'RDDIM(0Dh)' is shown in the Host area, with an arrow pointing down to a parallelogram shape in the Driver area. The parallelogram contains the text: '1st Parameter: Dummy Read' and '2nd Parameter: Send D[7:0] display image mode status'. To the right of the flow chart is a legend box with a dashed border, containing symbols for Command (trapezoid), Parameter (parallelogram), Display (rounded rectangle), Action (arrow), Mode (oval), and Sequential transfer (oval with arrow).</p> |              |     |       |    |    |    |    |    |         |    |    |     |         |               |  |                      |   |        |   |        |  |     |          |             |

| Flow Chart                               | <p>The flow chart illustrates the RDDSM(0Eh) command sequence. A Host sends the RDDSM(0Eh) command to the Driver. The Driver responds with two parameters: a Dummy Read (1st Parameter) and the display signal mode status (2nd Parameter). A legend defines the symbols used: a trapezoid for Command, a parallelogram for Parameter, a rounded rectangle for Display, a diamond for Action, a rounded rectangle for Mode, and a rounded rectangle with a curved arrow for Sequential transfer.</p>   |   |                                      |       |    |    |    |    |    |    |    |    |     |        |               |  |        |   |                         |   |                        |  |     |                            |     |                            |    |   |                                      |   |                                     |    |   |                                    |   |                                   |    |   |   |   |  |    |   |                                     |   |                                    |    |   |          |    |   |          |

| Description                               | This command is used to transfer data from MCU to frame memory. This command makes no change to the other driver status. When this command is accepted, the column register and the page register are reset to the Start Column/Start Page positions. The Start Column/Start Page positions are different in accordance with MADCTL setting.) Then D [17:0] is stored in frame memory and the column register and the page register incremented. Sending any other command can stop frame Write. X = Don't care.  |     |     |           |    |    |    |    |    |    |    |    |     |        |               |  |                                    |   |                                   |   |                                   |  |     |          |     |

| Description                               | <p>This command transfers image data from ILI9341's frame memory to the host processor starting at the pixel location specified by preceding set_column_address and set_page_address commands.</p> <p><b>If Memory Access control B5 = 0:</b></p> <p>The column and page registers are reset to the Start Column (SC) and Start Page (SP), respectively. Pixels are read from frame memory at (SC, SP). The column register is then incremented and pixels read from the frame memory until the column register equals the End Column (EC) value. The column register is then reset to SC and the page register is incremented. Pixels are read from the frame memory until the page register equals the End Page (EP) value or the host processor sends another command.</p> <p><b>If Memory Access Control B5 = 1:</b></p> <p>The column and page registers are reset to the Start Column (SC) and Start Page (SP), respectively. This command defines read/write scanning direction of frame memory.

This command makes no change on the other driver status.

| Bit | Name                     | Description   |
|-----|--------------------------|---|
| MY  | Row Address Order        | These 3 bits control MCU to memory write/read direction.                              |
| MX  | Column Address Order     |   |
| MV  | Row / Column Exchange    |   |

| BGR | RGB-BGR Order            | Color selector switch control<br>(0=RGB color filter panel, 1=BGR color filter panel) |
| MH  | Horizontal Refresh ORDER | LCD horizontal refreshing direction control.  |

Note: When BGR bit is changed, the new setting is active immediately without update the content in Frame Memory again.

X = Don't care.

| Description                               | <p>This command sets the pixel format for the RGB image data used by the interface. DPI [2:0] is the pixel format select of RGB interface and DBI [2:0] is the pixel format of MCU interface. If a particular interface, either RGB interface or MCU interface, is not used then the corresponding bits in the parameter are ignored. | Description               | <p>This command transfers image data from the host processor to the display module's frame memory continuing from the pixel location following the previous write_memory_continue or write_memory_start command.</p> <p><b>If set_address_mode B5 = 0:</b></p> <p>Data is written continuing from the pixel location after the write range of the previous write_memory_start or write_memory_continue. The column register is then incremented and pixels are written to the frame memory until the column register equals the End Column (EC) value. The column register is then reset to SC and the page register is incremented. Pixels are written to the frame memory until the page register equals the End Page (EP) value and the column register equals the EC value, or the host processor sends another command. If the number of pixels exceeds (EC – SC + 1) * (EP – SP + 1) the extra pixels are ignored.</p> <p><b>If set_address_mode B5 = 1:</b></p> <p>Data is written continuing from the pixel location after the write range of the previous write_memory_start or write_memory_continue. | Restriction                               | A read_memory_start should follow a set_column_address, set_page_address or set_address_mode to define the read location. Otherwise, data read with read_memory_continue is undefined.   |     |     |               |           |           |           |           |           |           |           |           |            |        |               |  |             |   |           |   |           |  |     |          |     |

| Flow Chart                                | <p>The flow chart illustrates the communication between the Host and the Driver for the RDID3(DCh) command. The Host sends the RDID3(DCh) command to the Driver. The Driver then returns two parameters: the 1st Parameter is a Dummy Read, and the 2nd Parameter is the Send ID3[7:0]. A legend on the right defines the symbols used: a trapezoid for Command, a parallelogram for Parameter, a rounded rectangle for Display, a chevron for Action, a rounded rectangle for Mode, and a rounded rectangle with a curved arrow for Sequential transfer.</p> |                                   |     |       |           |    |    |    |    |    |    |    |     |        |                                    |  |                   |   |           |   |        |  |          |          |           |

**GS:** Sets the direction of scan by the gate driver in the range determined by SCN [4:0] and NL [4:0]. The scan direction determined by GS = 0 can be reversed by setting GS = 1.

| GS | Gate Output Scan Direction |
|----|----------------------------|
| 0  | G1 → G320                  |
| 1  | G320 → G1                  |

**SM:** Sets the gate driver pin arrangement in combination with the GS bit to select the optimal scan mode for the module.

**NL [5:0]:** Sets the number of lines to drive the LCD at an interval of 8 lines. The GRAM address mapping is not affected by the number of lines set by NL [5:0]. The number of lines must be the same or more than the number of lines necessary for the size of the liquid crystal panel.

In Deep Standby mode, both internal logic power and SRAM power are turn off, the display data stored in the Frame Memory and the instructions are not saved. | <p>The graph shows a cumulative distribution function (CDF) curve for grayscale data. The x-axis is labeled 'Gray Scales' and ranges from 0 to 255. The y-axis is labeled 'Histogram' and ranges from 0% to 100%. A vertical line is drawn at a threshold value 'Dth' on the x-axis. A horizontal line is drawn from the intersection of this vertical line and the curve to the y-axis. This horizontal line is labeled with the bit fields TH_MV[3:0], TH_ST[3:0], and TH_UI[3:0].</p> |  |             |             |             |           |           |           |           |           |           |           |           |     |             |             |             |             |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |             |             |             |             |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |      |     |

**MY\_EOR / MX\_EOR / MV\_EOR / BGR\_EOR:**

The set value of MADCTL is used in the IC is derived as exclusive OR between 1st Parameter of IFCTL and MADCTL Parameter.

**MDT [1:0]:** Select the method of display data transferring.

**WEMODE:** Memory write control

WEMODE=0: When the transfer number of data exceeds (EC-SC+1)\*(EP-SP+1), the exceeding data will be ignored.

WEMODE=1: When the transfer number of data exceeds (EC-SC+1)\*(EP-SP+1), the column and page number will be reset, and the exceeding data will be written into the following column and page.

**ENDIAN:** Select Little Endian Interface bit. At Little Endian mode, the host sends LSB data first.

| ENDIAN | Data transfer Mode          |
|--------|-----------------------------|
| 0      | Normal (MSB first, default) |
| 1      | Little Endian (LSB first)   |

Note: Little Endian is valid on only 65K 8-bit and 9-bit MCU interface mode.

Description

**DM [1:0]:** Select the display operation mode.

| DM [1] | DM [0] | Display Operation Mode   |
|--------|--------|--------------------------|
| 0      | 0      | Internal clock operation |
| 0      | 1      | RGB Interface Mode       |
| 1      | 0      | VSYNC interface mode     |
| 1      | 1      | Setting disabled         |

The DM [1:0] setting allows switching between internal clock operation mode and external display interface operation mode.

However, switching between the RGB interface operation mode and the VSYNC interface operation mode is prohibited.

**RM:** Select the interface to access the GRAM.

Set RM to "1" when writing display data by the RGB interface.

| RM | Interface for RAM Access         |
|----|----------------------------------|
| 0  | System interface/VSYNC interface |
| 1  | RGB interface                    |

**RIM:** Specify the RGB interface mode when the RGB interface is used. These bits should be set before display operation through the RGB interface and should not be set during operation.

| RIM | COLMOD [6:4]     | RGB Interface Mode                       |
|-----|------------------|--|
| 0   | 110 (262K color) | 18- bit RGB interface (1 transfer/pixel) |
|     | 101 (65K color)  | 16- bit RGB interface (1 transfer/pixel) |
| 1   | 110 (262K color) | 6- bit RGB interface (3 transfer/pixel)  |
|     | 101 (65K color)  | 6- bit RGB interface (3 transfer/pixel)  |

**EPF [1:0]:** 65K color mode data format.

## 9. Display Data RAM

### 9.1. Configuration

The display data RAM stores display dots and consists of 1,382,400 bits (240x18x320 bits). There is no restriction on access to the RAM even when the display data on the same address is loaded to DAC. There will be no abnormal visible effect on the display when there is a simultaneous panel read and interface read or write display data to the same location of the frame memory.

## 9.2. Memory to Display Address Mapping

### 9.2.1. Normal Display ON or Partial Mode ON, Vertical Scroll Mode OFF

In this mode, the content of frame memory within an area where column pointer is 0000h to 00EFh and page pointer is 0000h to 013Fh is displayed.

To display a dot on leftmost top corner, store the dot data at (column pointer, page pointer) = (0, 0)

**9.2.2. Vertical Scroll Mode**

There is a vertical scrolling mode, which is determined by the commands “Vertical Scrolling Definition” (33h) and “Vertical Scrolling Start Address” (37h).

The Vertical Scroll Mode function is explained by these examples in the following.

TFA=2, VSA=318, BFA=0 when MADCTL ML bit = 0

TFA=2, VSA=316, BFA=2 when MADCTL ML bit = 0

TFA=2, VSA=316, BFA=4 when MADCTL ML bit = 0

Note: When Vertical Scrolling Definition Parameters (TFA+VSA+BFA) ≠ 320, Scrolling Mode is undefined.

**9.2.3. Vertical Scroll Example**

**9.2.4. Case1: TFA+VSA+BFA < 320**

This setting is prohibited, unless unexpected picture will be shown.

**9.2.5. Case2: TFA+VSA+BFA = 320 (Rolling Scrolling)**

The operation of Rolling Scrolling is explained by these examples in the following.

When TFA=0, VSA=320, BFA=0, VSCRSADD=40 and MADCTL ML bit = 1

When TFA=0, VSA=320, BFA=0, VSCRSADD=40 and MADCTL ML bit = 0

When TFA=30, VSA=290, BFA=0, VSCRSADD=80 and MADCTL ML bit = 0

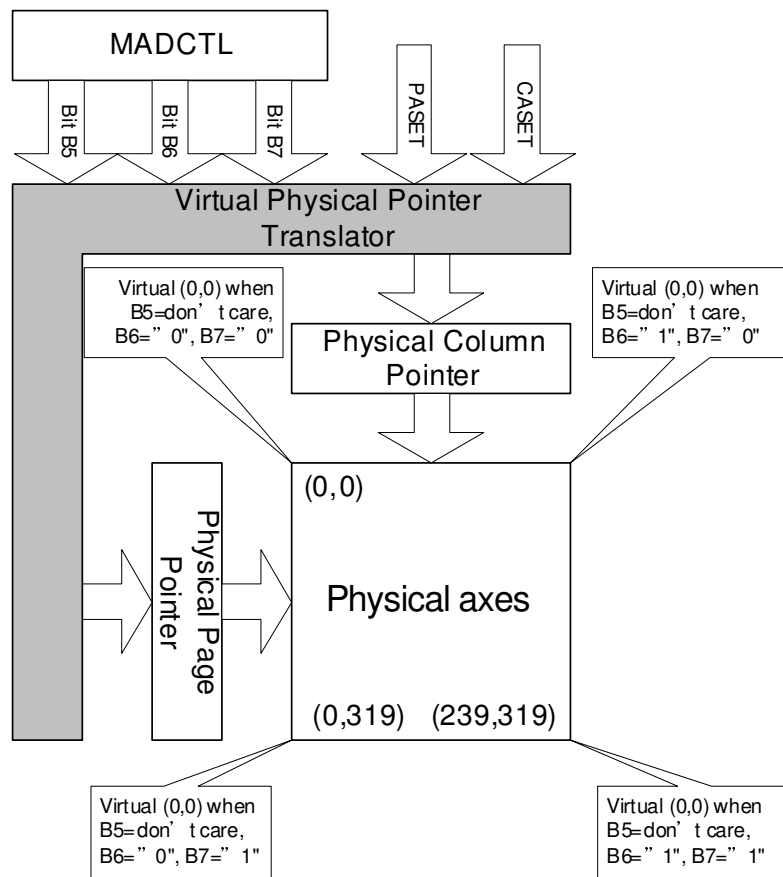

When TFA=30, VSA=290, BFA=0, VSCRSADD=80 and MADCTL ML bit = 1

### 9.3. MCU to memory write/read direction

The data is written in the order illustrated above. The Counter which dictates where in the physical memory the data is to be written is controlled by “Memory Data Access Control” Command, Bits B5, B6, and B7 as described below.

Note:

Data is always written to the Frame Memory in the same order, regardless of the Memory Write Direction set by MADCTL bits B7, B6 and B5. The write order for each pixel unit is

|     |     |     |     |     |     |     |     |    |    |    |    |    |    |    |    |    |    |

| R5  | R4  | R3  | R2  | R1  | R0  | G5  | G4  | G3 | G2 | G1 | G0 | B5 | B4 | B3 | B2 | B1 | B0 |

One pixel unit represents 1 column and 1 page counter value on the Frame Memory.

## 10. Tearing Effect Output

The Tearing Effect output line supplies to the MCU a Panel synchronization signal. This signal can be enabled or disabled by the Tearing Effect Line Off & On commands. The mode of the Tearing Effect Signal is defined by the parameter of the Tearing Effect Line Off & On commands.

The signal can be used by the MCU to synchronize Frame Memory Writing when displaying video images.

### 10.1. Tearing Effect Line Modes

**Mode 1**, the Tearing Effect Output signal consists of V-Sync information only:

tvdh = The LCD display is not updated from the Frame Memory.

tvdl = The LCD display is updated from the Frame Memory (except Invisible Line – see below).

**Mode 2**, the tearing effect output signal consists of V-Sync and H-Sync information; there is one V-sync and 320 H-sync pulses per field:

thdh = The LCD display is not updated from the Frame Memory.

thdl = The LCD display is updated from the Frame Memory (except Invisible Line – see above).

*Note: During Sleep In Mode, the Tearing Effect Output Pin is active Low.*

## 10.2. Tearing Effect Line Timings

The tearing effect signal is described below:

AC characteristics of Tearing Effect Signal (Frame Rate = 60Hz)

| Symbol    | Parameter                       | Min. | Typ. | Max. | Unit | Description |

Note:

1. The timings in Table as above apply when MADCTL B4=0 and B4=1
2. The signal's rise and fall times ( $t_f$ ,  $t_r$ ) are stipulated to be equal to or less than 15ns.

The Tearing Effect Output Line is fed back to the MCU and should be used to avoid Tearing Effect.

## 11. Sleep Out – Command and Self-Diagnostic Functions of the Display Module

### 11.1. Register loading Detection

Sleep Out-command (Command “Sleep Out (11h)”) is a trigger for an internal function of the display module, which indicates, if the display module loading function of factory default values from EV Memory(or similar device) to registers of the display controller is working properly.

If the register loading detection is successfully, there is inverted (= increased by 1) a bit, which is defined in command “Read Display Self-Diagnostic Result (0Fh)” (= RDDSDR) (The used bit of this command is D7). If it is failure, this bit (D7) is not inverted (= not increased by 1).

The flow chart for this internal function is following:

## 11.2. Functionality Detection

Sleep Out-command (Command “Sleep Out (11h)”) is a trigger for an internal function of the display module, which indicates, if the display module is still running and meets functionality requirements.

The internal function (= the display controller) is comparing, if the display module is still meeting functionality requirements (e.g. booster voltage levels, timings, etc.) If functionality requirement is met, there is an inverted (= increased by 1) bit, which defined in command “Read Display Self- Diagnostic Result (0Fh)” (= RDDSDR) (The used bit of this command is D6). If functionality requirement is not same, this bit (D6) is not inverted (= increased by 1). The flow chart for this internal function is shown as below.

The flow chart for this internal function is following:

*Note 1: There is needed 120msec after Sleep Out -command, when there is changing from Sleep In -mode to Sleep Out -mode, before there is possible to check if User's functionality requirements are met and a value of RDDSDR's D6 is valid. Otherwise, there is 5msec delay for D6's value, when Sleep Out -command is sent in Sleep Out -mode.*

## 12. Power ON/OFF Sequence

VDDI and VCI can be applied in any order.

VCI and VDDI can be powered down in any order.

During power off, if LCD is in the Sleep Out mode, VCI and VDDI must be powered down minimum 120msec after RESX has been released.

During power off, if LCD is in the Sleep In mode, VDDI or VCI can be powered down minimum 0msec after RESX has been released.

CSX can be applied at any timing or can be permanently grounded. RESX has priority over CSX.

*Note 1: There will be no damage to the display module if the power sequences are not met.*

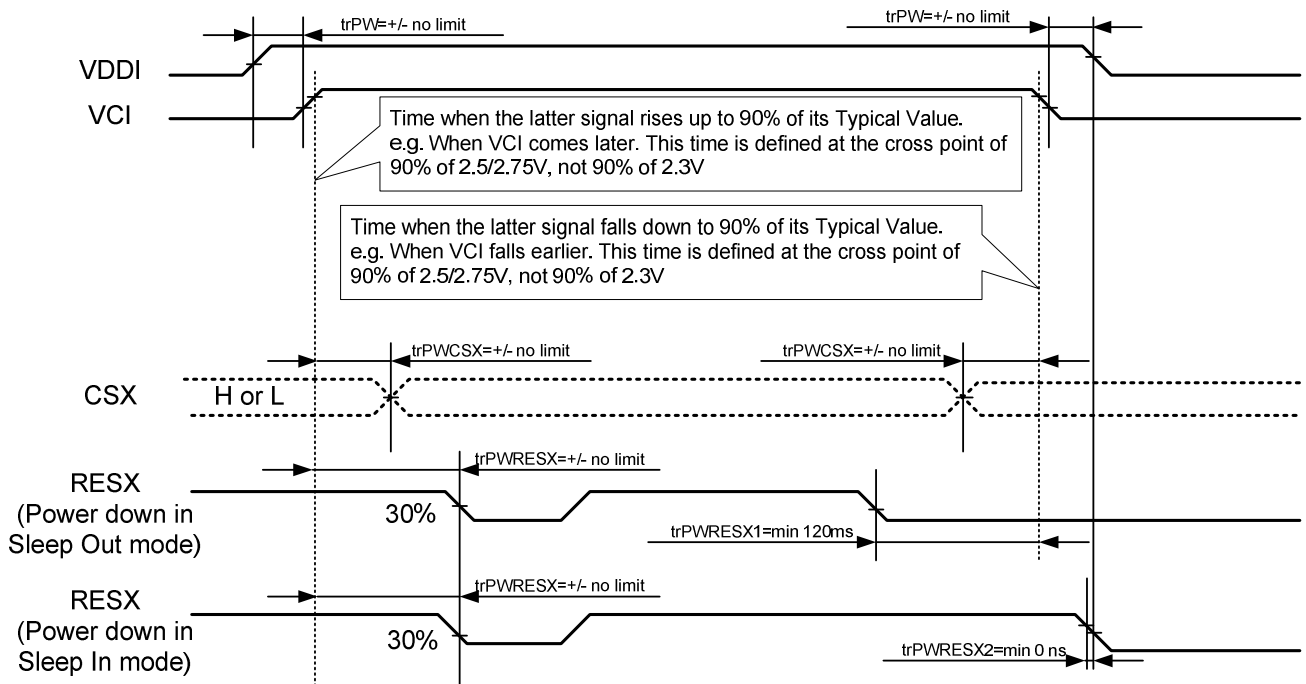

*Note 2: There will be no abnormal visible effects on the display panel during the Power On/Off Sequences.*

*Note 3: There will be no abnormal visible effects on the display between end of Power On Sequence and before receiving Sleep Out command. Also between receiving Sleep In command and Power Off Sequence.*

*Note 4: If RESX line is not held stable by host during Power On Sequence as defined in Sections 12.1 and 12.2, then it will be necessary to apply a Hardware Reset (RESX) after Host Power On Sequence is complete to ensure correct operation. Otherwise function is not guaranteed.*

### 12.1. Case 1 – RESX line is held High or Unstable by Host at Power ON

If RESX line is held High or unstable by the host during Power On, then a Hardware Reset must be applied after both VCI and VDDI have been applied – otherwise correct functionality is not guaranteed. There is no timing restriction upon this hardware reset.

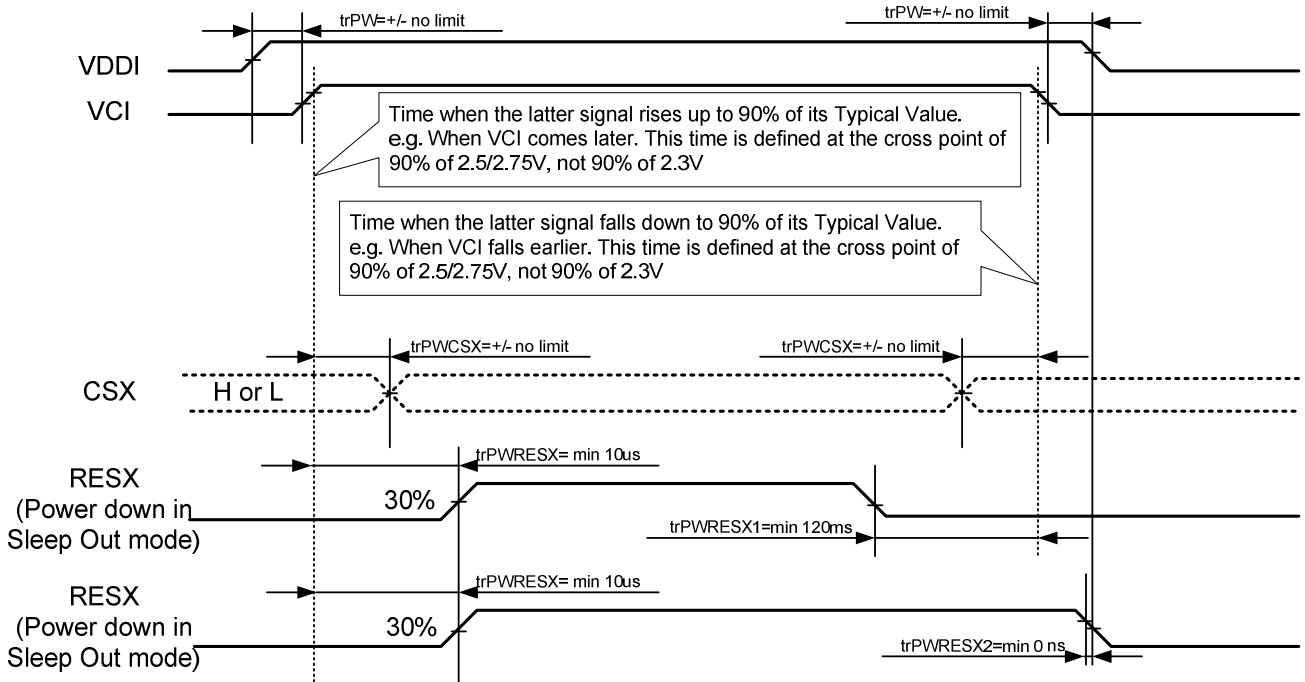

$trPWRESX1$  is applied to RESX falling in the Sleep Out Mode  
 $trPWRESX2$  is applied to RESX falling in the Sleep In Mode

*Note 1: Unless otherwise specified, timings herein show cross point at 50% of signal power level.*

*The information contained herein is the exclusive property of ILI Technology Corp. and shall not be distributed, reproduced, or disclosed in whole or in part without prior written permission of ILI Technology Corp.*

## 12.2. Case 2 – RESX line is held Low by Host at Power ON

If RESX line is held Low (and stable) by the host during Power On, then the RESX must be held low for minimum 10µsec after both VCI and VDDI have been applied.

trPWRESX1 is applied to RESX falling in the Sleep Out Mode  
trPWRESX2 is applied to RESX falling in the Sleep In Mode

Note 1: Unless otherwise specified, timings herein show cross point at 50% of signal power level.

### **12.3. Uncontrolled Power Off**

The uncontrolled power off means a situation when e.g. there is removed a battery without the controlled power off sequence. There will not be any damages for the display module or the display module will not cause any damages for the host or lines of the interface. At an uncontrolled power off event, ILI9341 will force the display to blank and will not be any abnormal visible effects with in 1 second on the display and remains blank until “Power On Sequence” actives.

## 13. Power Level Definition

### 13.1. Power Levels

7 level modes are defined they are in order of Maximum Power consumption to Minimum Power Consumption:

1. Normal Mode On (full display), Idle Mode Off, Sleep Out.

In this mode, the display is able to show maximum 262,144 colors.

2. Partial Mode On, Idle Mode Off, Sleep Out.

In this mode part of the display is used with maximum 262,144 colors.

3. Normal Mode On (full display), Idle Mode On, Sleep Out.

In this mode, the full display area is used but with 8 colors.

4. Partial Mode On, Idle Mode On, Sleep Out.

In this mode, part of the display is used but with 8 colors.

5. Sleep In Mode.

In this mode, the DC : DC converter, Internal oscillator and panel driver circuit are stopped. Only the MCU interface and memory works with VDDI power supply. Contents of the memory are safe.

6. Deep Standby Mode.

In Deep Standby mode, both internal logic power and SRAM power are turn off, the display data stored in the Frame Memory and the instructions are not saved. Rewrite Frame Memory content and instructions after the Deep Standby Mode is exited.

7. Power Off Mode.

In this mode, both VCI and VDDI are removed.

*Note1: Transition between modes 1-5 is controllable by MCU commands. Mode 6 is entered only when both Power supplies are removed.*

### 13.2. Power Flow Chart

*Note 1: There is not any abnormal visual effect when there is changing from one power mode to another power mode.*

*Note 2: There is not any limitation, which is not specified by User, when there is changing from one power mode to another power mode.*

## 14. Gamma Curves Selection

ILI9341 provide one gamma curve Gamma2.2. The gamma curve can be selected by the GC0 settings.

Note 1: There will be no abnormal visible effects on the display when S/W or H/W Resets are applied.

Note 2: After Powered-On Reset finishes within 10 $\mu$ s after both VCI & VDDI are applied.

Note 3: Mode 1 means Tearing Effect Output Line consists of V-Blanking Information only.

Note 4: When a RESX input is entered into the ILI9341 while it is in deep standby mode, the ILI9341 starts up the inside logic regulator and makes a transition to the initial state. During this period, the state of the interface pins may become unstable.

### 15.4. Reset Timing

| Signal | Symbol | Parameter            | Min | Max                 | Unit |
|--------|--------|----------------------|-----|---------------------|------|
| RESX   | tRW    | Reset pulse duration | 10  |                     | uS   |
|        | tRT    | Reset cancel         |     | 5<br>(note 1,5)     | mS   |
|        |        |                      |     | 120<br>(note 1,6,7) | mS   |

Note 1: The reset cancel includes also required time for loading ID bytes, VCOM setting and other settings from NV memory to registers. This loading is done every time when there is HW reset cancel time (tRT) within 5 ms after a rising edge of RESX.

Note 2: Spike due to an electrostatic discharge on RESX line does not cause irregular system reset according to the table below: -

| RESX Pulse           | Action         |
|----------------------|----------------|
| Shorter than 5us     | Reset Rejected |
| Longer than 10us     | Reset          |
| Between 5us and 10us | Reset starts   |

Note 3: During the Resetting period, the display will be blanked (The display is entering blanking sequence, which maximum time is 120 ms, when Reset Starts in Sleep Out –mode. The display remains the blank state in Sleep In -mode.) And then return to Default condition for Hardware Reset.

Note 4: Spike Rejection also applies during a valid reset pulse as shown below:

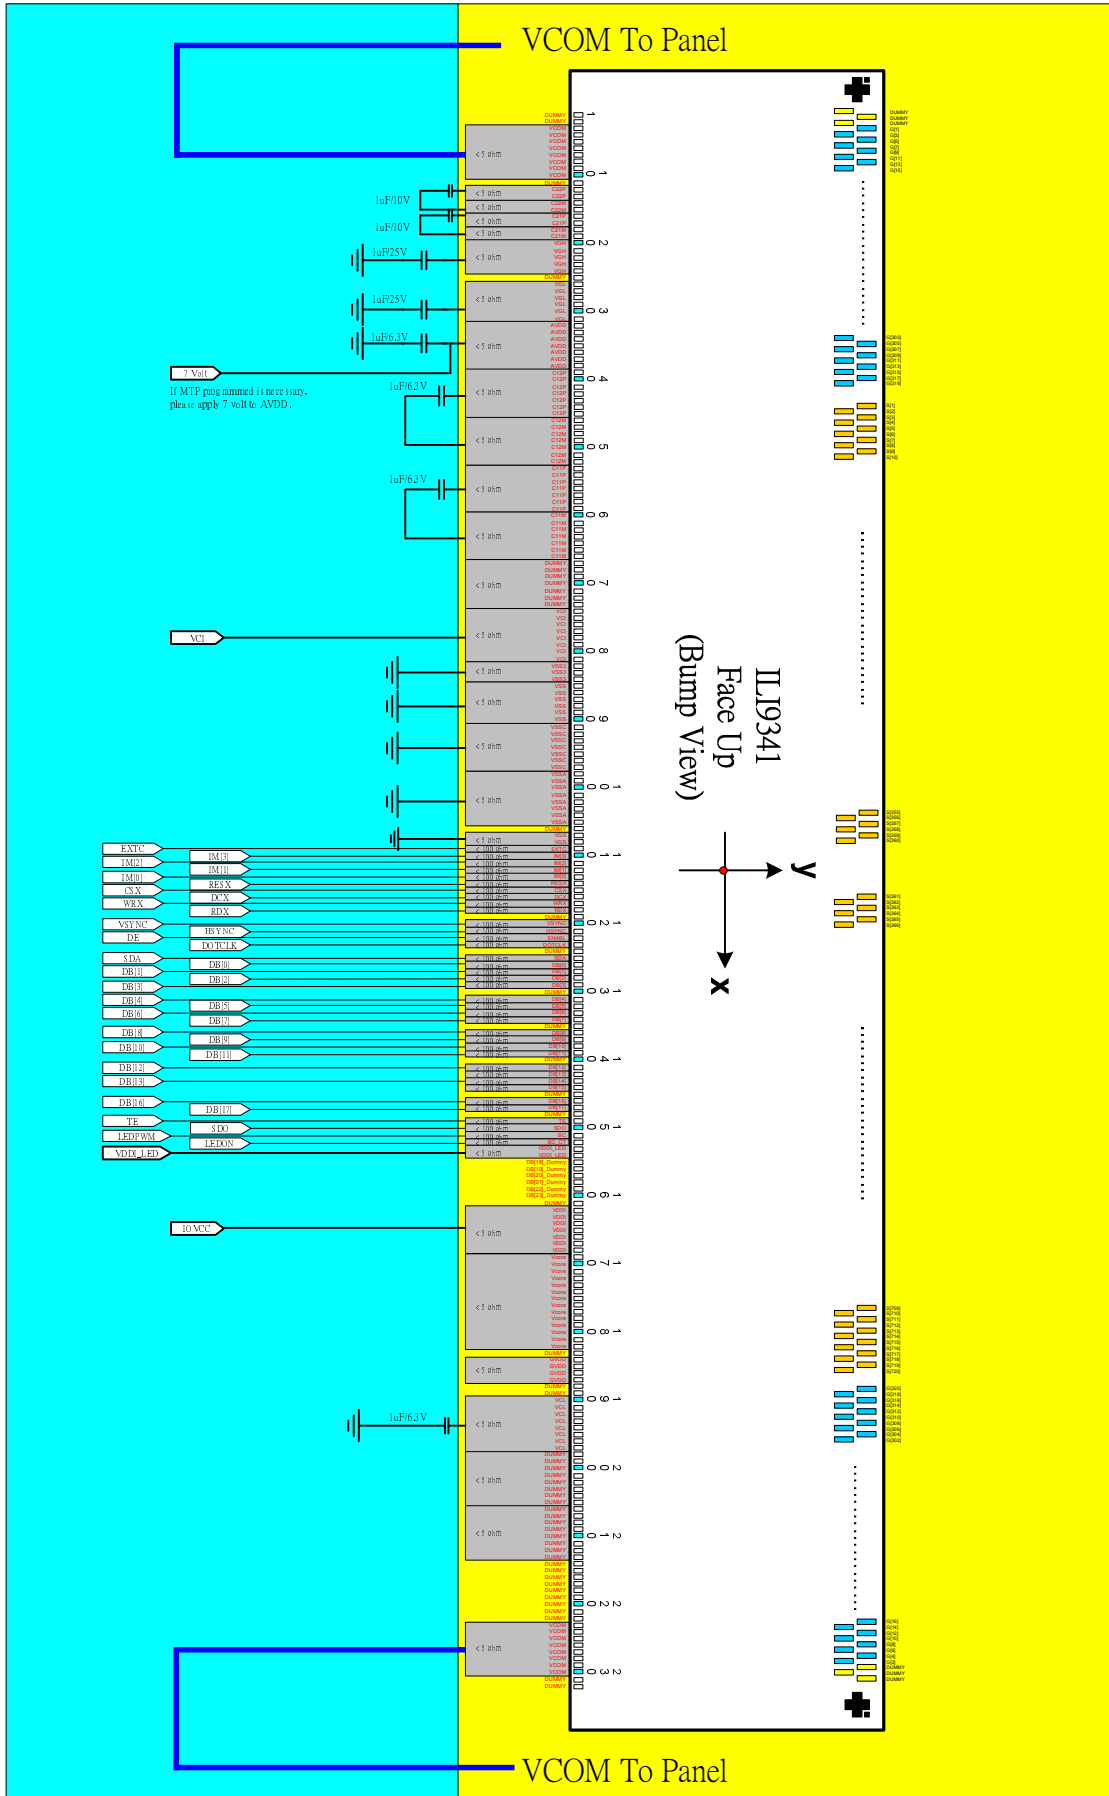

Note 5: When Reset applied during Sleep In Mode.

Note 6: When Reset applied during Sleep Out Mode.

Note 7: It is necessary to wait 5msec after releasing RESX before sending commands. Also Sleep Out command cannot be sent for 120msec.

## 16. Configuration of Power Supply Circuit

The Following tables shows specifications of external elements connected to the ILI9341's power supply circuit.

| Items                                     | Recommended Specification | Pin connection           |
|---|---------------------------|--------------------------|
| Capacity<br>1 $\mu$ F (B characteristics) | 6.3V                      | AVDD ,VGL,C11P/M,C12P/M, |
|   | 10V                       | C21P/M,C22P/M            |
|   | 25V                       | VGL, VGH                 |

## 17. NV Memory Programming Flow

## 18. Deep Standby Mode Setting

Note: (1) To Return display mode according to normal display ON sequence when ILI9341 exits Deep standby mode to Sleep mode.

(2) Leave at least 1ms between the 2<sup>nd</sup> and 3<sup>rd</sup> inputs of CSX=Low.

(3) This sequence must be completed before writing data to GRAM.

(4) ILI9341 exits deep standby mode and enters to sleep mode when an effective RESX pulse is inputted during Deep Standby mode.

## 19. Electrical Characteristics

### 19.1. Absolute Maximum Ratings

The absolute maximum rating is listed on following table. When ILI9341 is used out of the absolute maximum ratings, ILI9341 may be permanently damaged. To use ILI9341 within the following electrical characteristics limitation is strongly recommended for normal operation. If these electrical characteristic conditions are exceeded during normal operation, ILI9341 will malfunction and cause poor reliability.

| Item  | Symbol  | Unit | Value             |
|---|---------|------|-------------------|
| Supply voltage  | VCI     | V    | -0.3 ~ +4.6       |
| Supply voltage (Logic)  | VDDI    | V    | -0.3 ~ +4.6       |
| Supply voltage (Digital)  | VCORE   | V    | -0.3 ~ +2.0       |
| Driver supply voltage   | VGH-VGL | V    | -0.3 ~ +32.0      |
| Logic input voltage range   | VIN     | V    | -0.3 ~ VDDI + 0.3 |
| Logic output voltage range  | VO      | V    | -0.3 ~ VDDI + 0.3 |
| Operating temperature   | Topr    | °C   | -40 ~ +85         |
| Storage temperature   | Tstg    | °C   | -55 ~ +110        |
| <p><i>Note: If the absolute maximum rating of even is one of the above parameters is exceeded even momentarily, the quality of the product may be degraded. Absolute maximum ratings, therefore, specify the values exceeding which the product may be physically damaged. Be sure to use the product within the range of the absolute maximum ratings.</i></p> |         |      |                   |
